\$v\$, \$v *\$, *.target { color: Crimson }

Consider a dataset $D=\{(x_i,y_i)\}^N$ of N data points, where $x_i=(x_{i1},x_{i2},\cdots,x_{iM})$ is a feature vector with M features, and $\pmb{y_i}$ is the target, i.e., the response, variable. Let x_j denote the jth variable in feature space. A typical linear regression model can then be expressed mathematically as:

$$\mathbf{y} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_M x_M$$

This model assumes that the relationships between the target variable y_i and features x_j are linear and can be captured in slope terms $\beta_1, \beta_2, \ldots, \beta_M$.
